**Abstract**— Clustering is used extensively in various fields to obtain information from data (anomalies detection and identifying important features). One of the most commonly used clustering procedures is partitional-based clustering. In the is partitional-based clustering, number of clustering or partition is predefined. In this study, K-mean, K-medoid and Fuzzy C-Mean (FCM) were compared in clustering ITS laboratory . Simulation study is also used in order to see the clustering result in some settings of data scenarios. internal dissipation rate and pseudoF are used as index validity. The result of simulation study is k-mean generally give more optimal result than others for clustering data without outlier. Contralsy, if the outlier asserted, k-medoid perform better. The result of clustering ITS laboratory gives optimal number cluster  $k=5$ .

**Key Word**—Cluster, K-Mean, K-Medoid, Fuzzy C Means, Fuzzy C-Medoid, Polynomial Fuzzy C-Means.

## I. INTRODUCTION

Clustering is the proces of classifying objects into different groups based on information obtained from data that explains the relationship between objects with principles to maximize the similarity between members of one class and minimize the similarity between classes. Primary goals of clustering include getting information from data (anomalies detection and identifying important features), and classifying data[3].

Clustering is broadly divided into hierarchical and non-hierarchical methods [8]. Hierarchical algorithms recursively find nested clusters either in a top-down (divisive) or bottom-up (agglomerative) fashion. This method is often computationally ineficient[1]. Non-hierarchical method is divided into several procedures. One of the easiest is partitinional methods (ie k-mean and k-medoid). Partitional algorithms find all the clusters simultaneously as a partition of the data and do not impose a hierarchical structure[3].

k-means clustering method is the probably the most well known as a partititional procedure. The algorithm starts with initial centers, one for each cluster. This center is called centroid. All the instances are then compared with this centroid by a distance (euclidean, manhattan, etc) and assigned to the closest centroid. In the next stage, new centroids for each cluster are computed by using average of vector of the objects assigned to the cluster. This procedure is repeated until the members of each cluster are unchanged. Because of using mean vector as the centroid, this method is extremely sensitive to outliers[4]. The acurracy of k-means procedure is also very dependent upon the choice of initial

centroids so that this method is sensitive with choosing the initial centroids[10]. K-medoid clustering is sometimes used, where representative objects called medoids are considered instead of centroids in order to get more robust result. Among many algorithm for k-medoids clustering, Partitioning Around Medoids (PAM) is known to be most powerful. Another approach that deals with outliers is C-means (FCM) algorithm by[2] that extend hard C-means clustering methods[6]. The aim of this study is to compare k-mean, k-medoid, and FCM performance by using simulated data with saveral scenario and implementation on a real data. In this study, we use k-mean, k-medoid, and FCM for grouping laboratories at Institut Teknologi of Sepuluh Nopember to evaluate the productivity of research development within each laboratory.

## II. BACKGROUND THEORY

### A. K-Mean Cluster

The K-means clustering algorithm is described in detail by [3]. An efficient version of the algorithm is presented here. The aim of the K-means algorithm is to divide M points in N dimensions into K clusters so that the within-cluster sum of squares is minimized. It is not practical to require that the solution has minimal sum of squares against all partitions, except when M, N are small and  $K = 2$ . We seek instead "local" optima, solutions such that no movement of a point from one cluster to another will reduce the within-cluster sum of squares. Here is the pseudocode from[7] describing the iterations[12]:

1. Choose the number of clusters
2. Choose the metric to use
3. Choose the method to pick initial centroids
4. Assign initial centroid
5. Assign cases to closest centroid
6. Calculate centroids
7. For  $j \leq \text{number cluster}$ , if centroid j was updated in the last iteration
  - a. Calculate sum of square within cluster
  - b. For  $i \leq \text{number cases in cluster}$ 
    - i. Compute sum of square within cluster  $k \neq j$  if case included.
    - ii. If sum of square within cluster  $k < \text{sum of square within cluster } j$ , case change cluster

### B. K-Medoids Cluster

In the k-medoids algorithm, rather than calculating the mean of the items in each cluster, a representative item, or medoid, is chosen for each cluster at each iteration. Medoids

for each cluster are calculated by finding object  $i$  within the cluster that minimizes sum of square within cluster [4].

### C. Fuzzy C-Mean

In fuzzy  $k$ -means clustering[2], each case has a set of degree of belonging relative to all clusters. It differs from previously presented  $k$ -means clustering where each case belongs only to one cluster at a time. In this algorithm, the centroid of a cluster ( $ck$ ) is the mean of all cases in the dataset, weighted by their degree of belonging to the cluster ( $\omega_k$ ).

$$c_k = \frac{\sum_i \omega_k(x_i) x_i}{\sum_i \omega_k(x_i)}.$$

The degree of belonging is a function of the distance of the case from the centroid, which includes a parameter controlling for the highest weight given to the closest case. It iterates until a user-set criterion is reached. Like the  $k$ -means clustering technique, this technique is also sensitive to initial clusters and local minima. It is particularly useful for dataset coming from area of research where partial belonging to classes is supported by theory.

### D. Validity Clustering

The performance of the algorithm was evaluated by the average percentage of correct classification (recovery rate) and the internal cluster dispersion rate of the final partition defined as[11]

$$ICD = 1 - \frac{SSB}{SST} = 1 - R^2$$

$$SSB = \sum_{j=1}^k d_{j0}^2 \quad SST = \sum_{\ell=1}^n d_{\ell}^2 \cdot d_{j0}^2$$

$d_{j0}^2$  is the Euclidean distance

between the  $j$ th cluster center vector and the overall sample mean vector,  $d_{\ell}^2$  is the Euclidean distance between the  $\ell$ th observation vector and the overall sample mean vector,  $k$  is the number of clusters,  $n$  is the number of observed vectors.

Another validity method used to determine the number of optimum groups is Pseudo F-statistic. The highest Pseudo F indicates that the group shows optimal results, where the diversity in the group is very homogeneous whereas the intergroup is very heterogeneous. Here's the formula of Pseudo F [9]

$$PseudoF = \frac{R^2 / (c - 1)}{(1 - R^2) / (n - c)}$$

## III. METHODOLOGY

For comparative study, simulation study with some scenario settings was used in this study. The second stage is the application of data on laboratory achievement in ITS. Scenario setting in simulation study uses combination of observation number (N): 50 observation without outliers, 500 observation without outlier and 200 observation with adding outliers (outlier ratio is 0,3 from 200); number of clusters (k): [2,3,4,5]; number of variables (p): [5,10,20,40]; the process of generating data is implemented by using R clusterGeneration package by Qu and Joe (2015) that has implemented algorithm proposed by [10] for generating

cluster population. Each scenario of simulation setting was analyzed using K-Mean, K-Medoid, and Fuzzy K-Mean methods to see the best performance by using icd rate and pseudoF validity index.

Furthermore, there is a grouping analysis on laboratory capability data available in ITS using the three clustering methods. In order to obtain the best clusters, it can be concluded which laboratory group has a high index of research achievement. Stages of analysis is performed starting from data preprocessing (i.e scalling data into range 0 1 and using imputation to treat missing value using K-Nearest Neighbour) . 5 nearest neighbour is defined by using laboratory neighbours in the same faculty rather than use all faculty. Furthermore, factor analysis was done to reduce the dimension of the variable and to group variables with high correlation in order to get easier interpretation of the clustering result. The next step is grouping the laboratory to assess the research achievements of each laboratory and then interpret the result. All the analysis is conducted by using R 3.3.0.

## IV. RESULT

### A. Simulation Study

Simulation study is used to see clustering performance among all methods on the several scenario simulation.

**Table 1.** Simulation of Observation Without Outlier

| Number of Variable | Number of Observation | Clustering Mrthod | Number of Cluster |        |         |        |
|--------------------|-----------------------|-------------------|-------------------|--------|---------|--------|
|                    |                       |                   | 2                 | 3      | 4       | 5      |
| 5                  | 50 (Without Outlier)  | K-Mean            | 0.5522            | 38.928 | 0.4088  | 33.985 |
|                    |                       | K-Medoid          | 0.5281            | 42.885 | 0.4602  | 27.57  |

|                    |                       | Fuzzy K-Mean      | 0.7601            | 52.175  | 0.7549 | 40.169 |
| 40                 | 50 (Without Outlier)  | K-Mean            | 0.6902            | 6.8802  | 0.7722 | 3.3192 |
|                    |                       | K-Medoid          | 0.6977            | 6.6444  | 0.778  | 3.2104 |
|                    |                       | Fuzzy K-Mean      | 0.6954            | 6.7149  | 0.7741 | 3.2826 |

|                          |              |        |        |        |        |
|--------------------------|--------------|--------|--------|--------|--------|
| 500 (Without<br>Outlier) | K-Mean       | 0.8555 | 27.936 | 0.8319 | 25.003 |
|                          | K-Medoid     | 0.8135 | 37.902 | 0.8355 | 24.365 |
|                          | Fuzzy K-Mean | 0.8572 | 27.551 | 0.8336 | 24.704 |

According to above table, in the case of without outliers asserted in data, the overall mean icd rate and mean pseudoF validity index obtained for k-medoid are generally better than others. But as number of observation increase, K-Mean method give the best result overall. Meanwhile if we look based on the number of variable, when the number of small variables (5) the best clustering method is K-mean, but when its variable increases (10, 20, 40), the clustering method that gives the best performance is K-Medoid. K-mean method has decreased performance as the number of variable is increased. The next simulation scenario, outliers are asserted.

**Table 2.** Simulation of With Observation Outlier

| Number of<br>Variable | Number of<br>Observation   | Clustering<br>Mrthod | Number of Cluster |         |        |         |
|-----------------------|----------------------------|----------------------|-------------------|---------|--------|---------|
|                       |                            |                      | 2                 |         | 3      |         |
|                       |                            |                      | ICD               | PseudoF | ICD    | PseudoF |
| 5                     | 200 (Ratio<br>Outlier 30%) | K-Mean               | 0.8969            | 29.645  | 0.7098 | 52.528  |

|                       |                            | K-Medoid             | 0.9147            | 7.9595  | 0.8224 | 13.769  |
|                       |                            | Fuzzy K-Mean         | 0.904             | 9.0617  | 0.8603 | 10.356  |

Based on table 2, As a whole K-Medoid look better than others. This is because k-medoid is a robust method when the observation contains outliers.

## B. Laboratory Data

Prior to analysis, preprocessing data is performed to reduce noise in the data, such as scaling, missing and outlier data. This needs to be addressed first so that the results are smoother and represent the conditions in the field well.

Scaling is done because the inter-variables have different denomination. So it should be standardized by scaling, which has a range of 0-1.

Missing data is overcome by using the K-Nearest Neighbor method with  $K = 5$  and the neighbor in the faculty itself. Per Jönsson and Claes Wohlin (2004) suggest that by relaxing the method rule with respect to neighboring selection, the method's capability remains high for large amounts of lost data without affecting the quality of imputation. In some instances, the nearest neighboring imputation method provides unbiased and consistent asymptotic estimators of population (or total) mean function, population distribution, and population number[4]. In this study there are three laboratories in the Faculty of Industrial Technology which are not included in the analysis due to

unavailability of data, they are the Laboratory of Mineral Processing Technology and Materials of Materials Engineering and Metallurgy, Development of Industrial Systems and Management majoring in Industrial Engineering and Chemical Reaction Engineering Department of Chemical Engineering.

**Table 3.** Number of Data Missing Each Faculty

| FTSP | FTIF | FBMT | FV | FTI | FTE |
|------|------|------|----|-----|-----|
| 103  | 6    | 0    | 0  | 25  | 0   |

Outlier data has been accommodated by the medoids method based on the median data. The median is a robust measure of outliers compared to the mean.

Furthermore, factor analysis was done to reduce the variable dimension quite a lot. Hoping it can be interpreted easily. Here's the result of factor analysis,

**Table 4.** Grouping Variables with Factor Analysis

Exploration of data was conducted to find out the characteristics of each Exploration of data was conducted to find out the characteristics of each variable and comparison between faculties. Showed from the figure for all factors, FTI has the highest value almost in all variables. Because FTI has the most majors and the largest number of labs. Unlike the Faculty of FBMT classified as a new faculty with only 1 department and 2 labs. Neither is for other faculty Graph of comparison of the characteristics of each variable and comparison between the faculty can be seen in the appendix.

Table 5 shows the summaries of icd rate and pseudoF comparison for every possible cluster (2:10) within each clustering method

Optimal value of icd rate and pseudoF validity index respectively is 0,25132 for FCM (m=1,1) with 10 cluster and 33,7178 for k-means with 6 cluster. Generally, optimal modelling result are obtained by minimum average of icd rate and maximum average of pseudoF. As shown in table 5, k-mean give the optimal results with average of icd rate (0,47561) and average of pseudoF (26,1617).

**Table 6.** Mean ICD and PseudoF from the Number of Cluster

| Clustering Method                             | ICD             | PseudoF         |
|---|-----------------|-----------------|
| K-Mean  | <b>0,475614</b> | <b>26,16165</b> |
| K-Medoid                                      | 0,523351        | 21,29468        |
| Fuzzy K-Mean dengan Parameter Fuzzy (m = 1,1) | 0,482786        | 25,47682        |
| Fuzzy K-Mean dengan Parameter Fuzzy (m = 1,5) | 0,535875        | 19,79876        |
| Fuzzy K-Mean dengan Parameter Fuzzy (m = 1,9) | 0,591366        | 15,52349        |

By looking scree plot on figure1, the icd rate index of k-means clustering decreases sharply untill k=5, and then slowly decreases later on so that optimal number of cluster for grouping the laboratory is defined by k=5.

**Figure 1.** Plotting k optimal**Figure 2.** Variable in 3<sup>rd</sup> Factor

To simplify the interpretation of clustering result, Figure 2 was obtained to show the pairs plot of all factor conducted by 31 variables. As we can see that observations with high factor 2 values tend to be grouped into cluster 3 (green). Cluster 1 (black) tend to contain high values of factor 3 (Profile) with low values of factor 1 (Activities Laboratory), factor 2 (Citation), factor 4 (International Publication) and medium to high values of factor 5 (Cooperation Research). Cluster 5 (light blue) tend to be contained by laboratories with high values of factor 5.

## V. CONCLUSION

The conclusions can be obtained from this research, the first when using the simulation data the case of without outliers asserted in data, the overall mean icd rate and mean pseudoF validity index obtained for k-medoid are generally better than others. But as number of observation increase, K-Mean method give the best result overall. Meanwhile if we look based on the number of variable, the clustering method that gives the best performance is K-Medoid. K-mean method has decreased performance as the number of variable is increased. The next simulation scenario, outliers are asserted. Mean while if any outliers in dataset As a whole K-Medoid look better than others. This is because k-medoid is a robust method when the observation contains outliers.

The second when applied to lab data Generally, optimal modelling result are obtained by minimum average of icd rate and maximum average of pseudoF. As shown in table 6, k-mean give the optimal results with average of icd rate (0,47561) and average of pseudoF (26,1617).
